Building Empirical Models

- Introduction to Empirical Models
- Simple Linear Regression
- Correlation
- Multiple Regression
- Other Aspects of Regression

Empirical Models

- Many problems in engineering and science involve exploring the relationships between two or more variables.
- **Regression analysis** is a statistical technique that is very useful for these types of problems.
- For example, in a chemical process, suppose that the yield of the product is related to the process–operating temperature.
- Regression analysis can be used to build a model to predict yield at a given temperature level.

Empirical Models

Oxygen and Hydrocarbon Levels

Observation Number	Hydrocarbon Level x (%)	Purity y (%)
1	0.99	90.01
2	1.02	89.05
3	1.15	91.43
4	1.29	93.74
5	1.46	96.73
6	1.36	94.45
7	0.87	87.59
8	1.23	91.77
9	1.55	99.42
10	1.40	93.65
11	1.19	93.54
12	1.15	92.52
13	0.98	90.56
14	1.01	89.54
15	1.11	89.85
16	1.20	90.39
17	1.26	93.25
18	1.32	93.41
19	1.43	94.98
20	0.95	87.33

Empirical Models

Scatter Diagram of oxygen purity versus hydrocarbon level.

Empirical Models

- Based on the scatter diagram, it is probably reasonable to assume that the mean of the random variable Y is related to x by the following **straight-line relationship**:

$$E(Y|x) = \mu_{Y|x} = \beta_0 + \beta_1 x$$

where the slope and intercept of the line are called **regression coefficients**.

- The **simple linear regression model** is given by

$$Y = \beta_0 + \beta_1 x + \epsilon$$

where ϵ is the random error term.

Empirical Models

- We think of the regression model as an empirical model.
- Suppose that the mean and variance of ϵ are 0 and σ^2 , respectively, then

$$E(Y|x) = E(\beta_0 + \beta_1 x + \epsilon) = \beta_0 + \beta_1 x + E(\epsilon) = \beta_0 + \beta_1 x$$

- The variance of Y given x is

$$V(Y|x) = V(\beta_0 + \beta_1 x + \epsilon) = V(\beta_0 + \beta_1 x) + V(\epsilon) = 0 + \sigma^2 = \sigma^2$$

Empirical Models

- The true regression model is a line of mean values:

$$\mu_{Y|x} = \beta_0 + \beta_1 x$$

where β_1 can be interpreted as the change in the mean of Y for a unit change in x .

- Also, the variability of Y at a particular value of x is determined by the error variance, σ^2 .
- This implies there is **a distribution of Y -values at each x** and that the variance of this distribution is the same at each x .

Empirical Models

The distribution of Y for a given value of x for the oxygen purity–hydrocarbon data.

Building Empirical Models

- Introduction to Empirical Models
- Simple Linear Regression
- Correlation
- Multiple Regression
- Other Aspects of Regression

Simple Linear Regression

- The case of simple linear regression considers a single **regressor** or **predictor** x and a **dependent** or **response variable** Y .
- The expected value of Y at each level of x is a random variable:

$$E(Y|x) = \beta_0 + \beta_1 x$$

- We assume that each observation, Y , can be described by the model

$$Y = \beta_0 + \beta_1 x + \epsilon$$

Simple Linear Regression

- Suppose that we have n pairs of observations $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$.

Deviations of the data from the estimated regression model.

Simple Linear Regression

- The **method of least squares** is used to estimate the parameters, β_0 and β_1 by minimizing the sum of the squares of the vertical deviations

Deviations of the data from the estimated regression model.

Simple Linear Regression

- The n observations in the sample can be expressed as

$$y_i = \beta_0 + \beta_1 x_i + \epsilon_i, \quad i = 1, 2, \dots, n$$

- The sum of the squares of the deviations of the observations from the true regression line is

$$L = \sum_{i=1}^n \epsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

Simple Linear Regression

$$L = \sum_{i=1}^n \epsilon_i^2 = \sum_{i=1}^n (y_i - \beta_0 - \beta_1 x_i)^2$$

The least squares estimators of β_0 and β_1 , say, $\hat{\beta}_0$ and $\hat{\beta}_1$, must satisfy

$$\left. \frac{\partial L}{\partial \beta_0} \right|_{\hat{\beta}_0, \hat{\beta}_1} = -2 \sum_{i=1}^n (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_i) = 0$$

$$\left. \frac{\partial L}{\partial \beta_1} \right|_{\hat{\beta}_0, \hat{\beta}_1} = -2 \sum_{i=1}^n (y_i - \hat{\beta}_0 - \hat{\beta}_1 x_i) x_i = 0$$

Simplifying these two equations yields

$$\begin{aligned} n\hat{\beta}_0 + \hat{\beta}_1 \sum_{i=1}^n x_i &= \sum_{i=1}^n y_i \\ \hat{\beta}_0 \sum_{i=1}^n x_i + \hat{\beta}_1 \sum_{i=1}^n x_i^2 &= \sum_{i=1}^n y_i x_i \end{aligned}$$

Simple Linear Regression

Definition

The **least squares estimates** of the intercept and slope in the simple linear regression model are

$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x}$$
$$\hat{\beta}_1 = \frac{\sum_{i=1}^n y_i x_i - \frac{\left(\sum_{i=1}^n y_i\right)\left(\sum_{i=1}^n x_i\right)}{n}}{\sum_{i=1}^n x_i^2 - \frac{\left(\sum_{i=1}^n x_i\right)^2}{n}}$$

where $\bar{y} = (1/n) \sum_{i=1}^n y_i$ and $\bar{x} = (1/n) \sum_{i=1}^n x_i$.

Simple Linear Regression

The **fitted** or **estimated regression line** is therefore

$$\hat{y} = \hat{\beta}_0 + \hat{\beta}_1 x$$

Note that each pair of observations satisfies the relationship

$$y_i = \hat{\beta}_0 + \hat{\beta}_1 x_i + e_i, \quad i = 1, 2, \dots, n$$

where $e_i = y_i - \hat{y}_i$ is called the **residual**. The residual describes the error in the fit of the model to the i th observation y_i .

Simple Linear Regression

Notation

$$S_{xx} = \sum_{i=1}^n (x_i - \bar{x})^2 = \sum_{i=1}^n x_i^2 - \frac{\left(\sum_{i=1}^n x_i\right)^2}{n}$$

$$S_{xy} = \sum_{i=1}^n (y_i - \bar{y})(x_i - \bar{x}) = \sum_{i=1}^n x_i y_i - \frac{\left(\sum_{i=1}^n x_i\right)\left(\sum_{i=1}^n y_i\right)}{n}$$

Example: Oxygen Purity

Oxygen and Hydrocarbon Levels

Observation Number	Hydrocarbon Level x (%)	Purity y (%)
1	0.99	90.01
2	1.02	89.05
3	1.15	91.43
4	1.29	93.74
5	1.46	96.73
6	1.36	94.45
7	0.87	87.59
8	1.23	91.77
9	1.55	99.42
10	1.40	93.65
11	1.19	93.54
12	1.15	92.52
13	0.98	90.56
14	1.01	89.54
15	1.11	89.85
16	1.20	90.39
17	1.26	93.25
18	1.32	93.41
19	1.43	94.98
20	0.95	87.33

We will fit a simple linear regression model to the oxygen purity data. The following quantities may be computed:

$$n = 20 \quad \sum_{i=1}^{20} x_i = 23.92 \quad \sum_{i=1}^{20} y_i = 1,843.21$$

$$\bar{x} = 1.1960 \quad \bar{y} = 92.1605$$

$$\sum_{i=1}^{20} y_i^2 = 170,044.5321 \quad \sum_{i=1}^{20} x_i^2 = 29.2892$$

$$\sum_{i=1}^{20} x_i y_i = 2,214.6566$$

$$S_{xx} = \sum_{i=1}^{20} x_i^2 - \frac{\left(\sum_{i=1}^{20} x_i\right)^2}{20} =$$

$$=$$

and

$$S_{xy} = \sum_{i=1}^{20} x_i y_i - \frac{\left(\sum_{i=1}^{20} x_i\right)\left(\sum_{i=1}^{20} y_i\right)}{20}$$

$$=$$

Example: Oxygen Purity

Therefore, the least squares estimates of the slope and intercept are

$$\hat{\beta}_1 = \frac{S_{xy}}{S_{xx}} =$$

and

$$\hat{\beta}_0 = \bar{y} - \hat{\beta}_1 \bar{x} =$$

The fitted simple linear regression model (with the coefficients reported to three decimal places) is

$$\hat{y} =$$

Example: Oxygen Purity

Scatter plot of oxygen purity y versus hydrocarbon level x and regression model $\hat{y} =$

Simple Linear Regression

- Estimating σ^2
- The error sum of squares is

$$SS_E = \sum_{i=1}^n e_i^2 = \sum_{i=1}^n (y_i - \hat{y}_i)^2$$

- It can be shown that the expected value of the error sum of squares is $E(SS_E) = (n - 2)\sigma^2$.

Simple Linear Regression

- Estimating σ^2
- An **unbiased estimator** of σ^2 is

$$\hat{\sigma}^2 = \frac{SS_E}{n - 2}$$

Prediction of New Observations

- If x_0 is the value of the regressor variable of interest,

$$\hat{Y}_0 = \hat{\beta}_0 + \hat{\beta}_1 x_0$$

is the point estimator of the new or future value of the response, Y_0 .

A $100(1 - \alpha) \%$ **prediction interval on a future observation** Y_0 at the value x_0 is given by

$$\begin{aligned} \hat{y}_0 - t_{\alpha/2, n-2} \sqrt{\hat{\sigma}^2 \left[1 + \frac{1}{n} + \frac{(x_0 - \bar{x})^2}{S_{xx}} \right]} \\ \leq Y_0 \leq \hat{y}_0 + t_{\alpha/2, n-2} \sqrt{\hat{\sigma}^2 \left[1 + \frac{1}{n} + \frac{(x_0 - \bar{x})^2}{S_{xx}} \right]} \end{aligned}$$

The value $\hat{y}_0$ is computed from the regression model $\hat{y}_0 = \hat{\beta}_0 + \hat{\beta}_1 x_0$.

$$\text{MAPE}(y, \hat{y}) = \frac{1}{n_{\text{samples}}} \sum_{i=0}^{n_{\text{samples}}-1} \frac{|y_i - \hat{y}_i|}{\max(\epsilon, |y_i|)}$$

Building Empirical Models

- Introduction to Empirical Models
- Simple Linear Regression
- Correlation
- Multiple Regression
- Other Aspects of Regression

Correlation

- Finding the relationship between two quantitative variables without being able to infer causal relationships
- **Correlation** is a statistical technique used to determine the degree to which two variables are related

Positive relationship

Positive relationship

Negative relationship

No Relationship

Correlation Coefficient

- Statistic showing the degree of relation between two variables
- Simple Correlation coefficient (r)
 - It is also called Pearson's correlation or product moment correlation coefficient.
 - It measures the nature and strength between two variables of the quantitative type.
- The **sign** of r denotes the nature of association
- while the **value** of r denotes the strength of association.

- If the sign is **+ve** this means the relation is **direct** (an increase in one variable is associated with an increase in the other variable and a decrease in one variable is associated with a decrease in the other variable).
- While if the sign is **-ve** this means an **inverse or indirect** relationship (which means an increase in one variable is associated with a decrease in the other).

- The value of r ranges between (-1) and ($+1$)
- The value of r denotes the strength of the association as illustrated by the following diagram.

- If $r = \text{Zero}$ this means no association or correlation between the two variables.
- If $0 < r < 0.25$ = weak correlation.
- If $0.25 \leq r < 0.75$ = intermediate correlation.
- If $0.75 \leq r < 1$ = strong correlation.
- If $r = 1$ = perfect correlation.

How to compute the simple correlation coefficient (r)

$$r = \frac{\sum xy - \frac{\sum x \sum y}{n}}{\sqrt{\left(\sum x^2 - \frac{(\sum x)^2}{n} \right) \left(\sum y^2 - \frac{(\sum y)^2}{n} \right)}}$$

Exercise

$$r = \frac{\sum xy - \frac{\sum x \sum y}{n}}{\sqrt{\left(\sum x^2 - \frac{(\sum x)^2}{n} \right) \left(\sum y^2 - \frac{(\sum y)^2}{n} \right)}}$$

$$r = ?$$

Building Empirical Models

- Introduction to Empirical Models
- Simple Linear Regression
- Correlation
- Multiple Regression
- Other Aspects of Regression

Multiple Linear Regression Models

- Many applications of regression analysis involve situations in which there are more than one regressor variable.
- A regression model that contains more than one regressor variable is called a **multiple regression model**.
- **For example**, suppose that the effective life of a cutting tool depends on the cutting speed and the tool angle. A possible multiple regression model could be

$$Y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \epsilon$$

where Y – tool life

x_1 – cutting speed

x_2 – tool angle

Multiple Linear Regression Models

(a) The regression plane for the model $E(Y) = 50 + 10x_1 + 7x_2$.

(b) The contour plot

Multiple Linear Regression Models

In general, the **dependent variable** or **response** Y may be related to k **independent** or **regressor variables**. The model

$$Y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \cdots + \beta_k x_k + \epsilon$$

is called a multiple linear regression model with k regressor variables. The parameters $\beta_j, j = 0, 1, \dots, k$, are called the regression coefficients. This model describes a hyperplane in the k -dimensional space of the regressor variables $\{x_j\}$. The parameter β_j represents the expected change in response Y per unit change in x_j when all the remaining regressors $x_i (i \neq j)$ are held constant.

Multiple Linear Regression Models

(a) Three-dimensional plot of the regression model $E(Y) = 50 + 10x_1 + 7x_2 + 5x_1x_2$.
(b) The contour plot

a) Three-dimensional plot of the regression model $E(Y) = 800 + 10x_1 + 7x_2 - 8.5x_1^2 - 5x_2^2 + 4x_1x_2$.
(b) The contour plot

Least Squares Estimation of the Parameters

The **method of least squares** may be used to estimate the regression coefficients in the multiple regression model. Suppose that $n > k$ observations are available, and let x_{ij} denote the i th observation or level of variable x_j . The observations are

$$(x_{i1}, x_{i2}, \dots, x_{ik}, y_i), \quad i = 1, 2, \dots, n \quad \text{and} \quad n > k$$

It is customary to present the data for multiple regression in a table.

Data for Multiple Linear Regression

y	x_1	x_2	$\dots$	x_k
y_1	x_{11}	x_{12}	$\dots$	x_{1k}
y_2	x_{21}	x_{22}	$\dots$	x_{2k}
$\vdots$	$\vdots$	$\vdots$		$\vdots$
y_n	x_{n1}	x_{n2}	$\dots$	x_{nk}

Least Squares Estimation of the Parameters

- The **least squares function** is given by

$$L = \sum_{i=1}^n \epsilon_i^2 = \sum_{i=1}^n \left(y_i - \beta_0 - \sum_{j=1}^k \beta_j x_{ij} \right)^2$$

- The **least squares estimates** must satisfy

$$\left. \frac{\partial L}{\partial \beta_0} \right|_{\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k} = -2 \sum_{i=1}^n \left(y_i - \hat{\beta}_0 - \sum_{j=1}^k \hat{\beta}_j x_{ij} \right) = 0$$

and

$$\left. \frac{\partial L}{\partial \beta_j} \right|_{\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k} = -2 \sum_{i=1}^n \left(y_i - \hat{\beta}_0 - \sum_{j=1}^k \hat{\beta}_j x_{ij} \right) x_{ij} = 0 \quad j = 1, 2, \dots, k$$

Least Squares Estimation of the Parameters

- The **least squares normal Equations** are

$$\begin{array}{ccccccc}
 n\hat{\beta}_0 + \hat{\beta}_1 \sum_{i=1}^n x_{i1} & + \hat{\beta}_2 \sum_{i=1}^n x_{i2} & + \cdots + \hat{\beta}_k \sum_{i=1}^n x_{ik} & = & \sum_{i=1}^n y_i \\
 \hat{\beta}_0 \sum_{i=1}^n x_{i1} + \hat{\beta}_1 \sum_{i=1}^n x_{i1}^2 & + \hat{\beta}_2 \sum_{i=1}^n x_{i1} x_{i2} & + \cdots + \hat{\beta}_k \sum_{i=1}^n x_{i1} x_{ik} & = & \sum_{i=1}^n x_{i1} y_i \\
 \vdots & \vdots & \vdots & & \vdots \\
 \hat{\beta}_0 \sum_{i=1}^n x_{ik} + \hat{\beta}_1 \sum_{i=1}^n x_{ik} x_{i1} & + \hat{\beta}_2 \sum_{i=1}^n x_{ik} x_{i2} & + \cdots + \hat{\beta}_k \sum_{i=1}^n x_{ik}^2 & = & \sum_{i=1}^n x_{ik} y_i
 \end{array}$$

- The solution to the normal Equations are the **least squares estimators** of the regression coefficients.

Example: Wire Bond Strength

- The data on **pull strength** of a wire bond in a semiconductor manufacturing process, **wire length** and **die height** are used to illustrate building an empirical model.

Wire Bond Data

Observation Number	Pull Strength y	Wire Length x_1	Die Height x_2	Observation Number	Pull Strength y	Wire Length x_1	Die Height x_2
1	9.95	2	50	14	11.66	2	360
2	24.45	8	110	15	21.65	4	205
3	31.75	11	120	16	17.89	4	400
4	35.00	10	550	17	69.00	20	600
5	25.02	8	295	18	10.30	1	585
6	16.86	4	200	19	34.93	10	540
7	14.38	2	375	20	46.59	15	250
8	9.60	2	52	21	44.88	15	290
9	24.35	9	100	22	54.12	16	510
10	27.50	8	300	23	56.63	17	590
11	17.08	4	412	24	22.13	6	100
12	37.00	11	400	25	21.15	5	400
13	41.95	12	500				

Example: Wire Bond Strength

- This figure shows a matrix of two-dimensional scatter plots of the data. These displays can be helpful in visualizing the relationships among variables in a multivariable data set. For example, the plot indicates that there is a strong linear relationship between strength and wire length.

Matrix of scatter plots for the wire bond pull strength data.

Example: Wire Bond Strength

Specifically, we will fit the multiple linear regression model

$$Y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \epsilon$$

where Y = pull strength, x_1 = wire length, and x_2 = die height.

$$n = \sum_{i=1}^{25} y_i =$$

$$\sum_{i=1}^{25} x_{i1} = \sum_{i=1}^{25} x_{i2} =$$

$$\sum_{i=1}^{25} x_{i1}^2 = \sum_{i=1}^{25} x_{i2}^2 =$$

$$\sum_{i=1}^{25} x_{i1} x_{i2} = \sum_{i=1}^{25} x_{i1} y_i =$$

$$\sum_{i=1}^{25} x_{i2} y_i =$$

Example: Wire Bond Strength

For the model $Y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \epsilon$, the normal equations are

$$n\hat{\beta}_0 + \hat{\beta}_1 \sum_{i=1}^n x_{i1} + \hat{\beta}_2 \sum_{i=1}^n x_{i2} = \sum_{i=1}^n y_i$$

$$\hat{\beta}_0 \sum_{i=1}^n x_{i1} + \hat{\beta}_1 \sum_{i=1}^n x_{i1}^2 + \hat{\beta}_2 \sum_{i=1}^n x_{i1}x_{i2} = \sum_{i=1}^n x_{i1}y_i$$

$$\hat{\beta}_0 \sum_{i=1}^n x_{i2} + \hat{\beta}_1 \sum_{i=1}^n x_{i1}x_{i2} + \hat{\beta}_2 \sum_{i=1}^n x_{i2}^2 = \sum_{i=1}^n x_{i2}y_i$$

Inserting the computed summations into the normal equations, we obtain

=
=
=

Example: Wire Bond Strength

The solution to this set of equations is

$$\hat{\beta}_0 = \quad \hat{\beta}_1 = \quad \hat{\beta}_2 =$$

Therefore, the fitted regression equation is

$$\hat{y} =$$

Practical Interpretation: This equation can be used to predict pull strength for pairs of values of the regressor variables wire length (x_1) and die height (x_2).

Matrix Approach to Multiple Linear Regression

- Suppose the model relating the regressors to the response is

$$y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \cdots + \beta_k x_{ik} + \epsilon_i \quad i = 1, 2, \dots, n$$

- In matrix notation this model can be written as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where

$$\mathbf{y} = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} \quad \mathbf{X} = \begin{bmatrix} 1 & x_{11} & x_{12} & \cdots & x_{1k} \\ 1 & x_{21} & x_{22} & \cdots & x_{2k} \\ \vdots & \vdots & \vdots & & \vdots \\ 1 & x_{n1} & x_{n2} & \cdots & x_{nk} \end{bmatrix} \quad \boldsymbol{\beta} = \begin{bmatrix} \beta_0 \\ \beta_1 \\ \vdots \\ \beta_k \end{bmatrix} \quad \text{and} \quad \boldsymbol{\epsilon} = \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_n \end{bmatrix}$$

Matrix Approach

- We wish to find the vector of least squares estimators that minimizes:

$$L = \sum_{i=1}^n \epsilon_i^2 = \epsilon' \epsilon = (y - X\beta)'(y - X\beta)$$

- The resulting least squares estimate is

$$\hat{\beta} = (X'X)^{-1} X'y$$

Matrix Approach

The fitted regression model is

$$\hat{y}_i = \hat{\beta}_0 + \sum_{j=1}^k \hat{\beta}_j x_{ij} \quad i = 1, 2, \dots, n$$

In matrix notation, the fitted model is

$$\hat{\mathbf{y}} = \mathbf{X}\hat{\boldsymbol{\beta}}$$

The difference between the observation y_i and the fitted value $\hat{y}_i$ is a **residual**, say, $e_i = y_i - \hat{y}_i$. The $(n \times 1)$ vector of residuals is denoted by

$$\mathbf{e} = \mathbf{y} - \hat{\mathbf{y}}$$

Example

The multiple regression model

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \epsilon$$

where y is the observed pull strength for a wire bond, x_1 is the wire length, and x_2 is the die height. The 25 observations are in the Table. We will now use the matrix approach to fit the regression model above to these data. The model matrix $\mathbf{X}$ and $\mathbf{y}$ vector for this model are

$\mathbf{X} =$	1	2	50	$\mathbf{y} =$	9.95
	1	8	110		24.45
	1	11	120		31.75
	1	10	550		35.00

	1	11	400		37.00
	1	12	500		41.95
	1	2	360		11.66
	1	4	205		21.65
	1	4	400		17.89
	1	20	600		69.00
	1	1	585		10.30
	1	10	540		34.93
	1	15	250		46.59
	1	15	290		44.88
	1	16	510		54.12
	1	17	590		56.63
	1	6	100		22.13
	1	5	400		21.15

Example

The $X'X$ matrix is

$$X'X = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 2 & 8 & \cdots & 5 \\ 50 & 110 & \cdots & 400 \end{bmatrix} \begin{bmatrix} 1 & 2 & 50 \\ 1 & 8 & 110 \\ \vdots & \vdots & \vdots \\ 1 & 5 & 400 \end{bmatrix}$$

$$= \begin{bmatrix} 25 & 206 & 8,294 \\ 206 & 2,396 & 77,177 \\ 8,294 & 77,177 & 3,531,848 \end{bmatrix}$$

and the $X'y$ vector is

$$X'y = \begin{bmatrix} 1 & 1 & \cdots & 1 \\ 2 & 8 & \cdots & 5 \\ 50 & 110 & \cdots & 400 \end{bmatrix} \begin{bmatrix} 9.95 \\ 24.45 \\ \vdots \\ 21.15 \end{bmatrix} = \begin{bmatrix} 725.82 \\ 8,008.47 \\ 274,816.71 \end{bmatrix}$$

The least squares estimates are found as

$$\hat{\beta} = (X'X)^{-1}X'y$$

Example

or

$$\begin{aligned}
 \begin{bmatrix} \hat{\beta}_0 \\ \hat{\beta}_1 \\ \hat{\beta}_2 \end{bmatrix} &= \begin{bmatrix} 25 & 206 & 8,294 \\ 206 & 2,396 & 77,177 \\ 8,294 & 77,177 & 3,531,848 \end{bmatrix}^{-1} \begin{bmatrix} 725.82 \\ 8,008.37 \\ 274,811.31 \end{bmatrix} \\
 &= \begin{bmatrix} 0.214653 & -0.007491 & -0.000340 \\ -0.007491 & 0.001671 & -0.000019 \\ -0.000340 & -0.000019 & +0.0000015 \end{bmatrix} \begin{bmatrix} 725.82 \\ 8,008.47 \\ 274,811.31 \end{bmatrix} \\
 &= \begin{bmatrix} 2.26379143 \\ 2.74426964 \\ 0.01252781 \end{bmatrix}
 \end{aligned}$$

Therefore, the fitted regression model with the regression coefficients rounded to five decimal places is

$$\hat{y} = 2.26379 + 2.74427x_1 + 0.01253x_2$$

Multiple Linear Regression Models

This regression model can be used to predict values of pull strength for various values of wire length (x_1) and die height (x_2). We can also obtain the **fitted values** $\hat{y}_i$ by substituting each observation (x_{i1}, x_{i2}), $i = 1, 2, \dots, n$, into the equation. For example, the first observation has $x_{11} = 2$ and $x_{12} = 50$, and the fitted value is

$$\begin{aligned}\hat{y}_1 &= 2.26379 + 2.74427x_{11} + 0.01253x_{12} \\ &= \\ &= \end{aligned}$$

The corresponding observed value is $y_1 = 9.95$. The *residual* corresponding to the first observation is

$$\begin{aligned}e_1 &= y_1 - \hat{y}_1 \\ &= \\ &= \end{aligned}$$

Multiple Linear Regression Models

This Table displays all 25 fitted values $\hat{y}_i$ and the corresponding residuals. The fitted values and residuals are calculated to the same accuracy as the original data.

Observations, Fitted Values, and Residuals

Observation Number	y_i	$\hat{y}_i$	$e_i = y_i - \hat{y}_i$	Observation Number	y_i	$\hat{y}_i$	$e_i = y_i - \hat{y}_i$
1	9.95	8.38	1.57	14	11.66	12.26	-0.60

Multiple Linear Regression Models

- Estimating σ^2
- An unbiased estimator of σ^2 is

$$\hat{\sigma}^2 = \frac{\sum_{i=1}^n e_i^2}{n - p} = \frac{SS_E}{n - p}$$

where p is the number of parameters.

Other Aspects of Regression

- Polynomial Models

- The second-order model in two regressors is

$$Y = \beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_{12}x_1x_2 + \beta_{11}x_1^2 + \beta_{22}x_2^2 + \epsilon$$

- Categorical Regressors

- Many problems may involve qualitative or categorical variables.
 - The usual method for the different levels of a qualitative variable is to use indicator variables.

- Variable Selection Procedures

- Best Subsets Regressions
